SUBADDITIVE PROBABILITIES AND PORTFOLIO INERTIA

Mario Henrique Simonsen*

Sérgio Ribeiro da Costa Werlang*

1) Introduction

Why small changes in relative asset prices do not necessarily lead to an immediate change in individual portfolios is an intriguing question in the theory of financial decisions. Portfolio rigidities may obviously be caused by transaction costs. Corner equilibria, which may emerge when short sales are ruled out can be another reason for inertia. Yet, in many empirical cases, a more powerful source of friction appears to be responsible for the lack of response of quantities to prices.

Subadditive probabilities provide the proper analytical tool to describe this stronger source of portfolio inertia. Formally, a subadditive probability space $(\Omega; \mathcal{A}; p)$ is a non-void set Ω (universe), an algebra $\mathcal{A}$ of subsets of Ω (measurable events), and a real valued function p defined for every element of $\mathcal{A}$, such that:

$$i) \quad p(\emptyset) = 0$$

$$ii) \quad p(\Omega) = 1$$

$$iii) \quad p\left(\bigcup_{n=1}^k A_n\right) \geq \sum_{n=1}^k p(A_n) \quad \text{for every finite collection of}$$

measurable and disjoint events.

* Professors at EPGE/FGV.

Subadditive Probabilities have been studied from the probabilistic viewpoint by Dempster(1967) and Shafer(1976).

A random variable X in a subadditive probability space is a real valued measurable function defined for every point $w \in \Omega$.

From the point of view of decision theory, Schmeidler (1982,1984), Gilboa(1987) and Gilboa and Schmeidler(1986) analyse subadditive probabilities. They describe a mix of pure risk and pure uncertainty according to Frank Knight's classical distinction (Knight(1921)). It means, in fact, incomplete information about the true probabilities. All that is known about the true probability $p'(B)$ of event B is that it is greater or equal than $p(B)$. Since $B \cup B^C = \Omega$, where B^C stands for the complement of B , $p(B) + p(B^C) \leq 1$, because of sigma subadditivity. As a consequence, all available information on the true probability of B is that $p(B) \leq p'(B) \leq 1 - p(B^C)$. The degree of uncertainty of event B can be measured by $1 - p(B) - p(B^C)$. From this point of view, Dow and Werlang(1989) define and examine a measure of uncertainty aversion (or degree of uncertainty).

An easy way to create a subadditive probability space is to take a family $(\Omega, \mathcal{A}, p_j)$ of probability spaces, for the same universe and the same algebra of measurable events, but different probability functions; then take:

$$p(B) = \inf_j \{p_j(B)\}$$

Conversely, one may easily prove that every subadditive probability space can be generated by a family of probability functions as above, as shown by Gilboa and Schmeidler(1986).

The attractiveness of the concept of subadditive probabilities is that it possibly provides the best possible description for what is behind the widespread notion of subjective probabilities in the theory of financial decisions. Probability theory gained its scientific prestige because phycisists, insurance companies and card players realized that the law of large numbers works in the real world. Now, the whole power of the theory was based on the existence of objective probabilities. Subjective probabilities where invented to translate uncertainty into a language where the theory of choice of involving risk could be easily used, and this was the base for the development of the theory of financial decisions. Except that it was probably a bad translation. The translation of uncertainty into risk by the use of additive subjective probabilities, was obtained by Savage(1954), and Wilson and Edmunds (1960), under very stringent conditions. Subjective probabilities suggest a lack of empirical information that, at best, allows the individual to estimate the probability of an event within a certain interval, and not as a precise real number. Now, this means describing subjective probabilities not by a conventional, but by a subadditive probability space, where the true probability of an event B lies in the interval $\left[p(B), 1-p(B^c) \right]$.

Incidentally, the extreme cases of pure risk and pure uncertainty can also be described by particular subadditive probability spaces. The case of pure risk, of course, corresponds to a conventional additive probability. Total uncertainty by $p(B) = 0$ for every measurable event such that $B^c \neq \emptyset$. This is the message that

except for the universe and the void set, the probability of any event B may lie in any point of the closed $[0;1]$ interval.

The crucial point is that optimization under pure risk and under pure uncertainty follows different criteria both incidentally explored in the von Neumann-Morgenstern seminal work on game theory (Von Neumann and Morgenstern(1947)). Under pure risk, the individual should maximize his expected utility given his budget constraint. Under pure uncertainty, there is no other possible advice but prudence, that leads to a maximin choice: the portfolio should be selected so as to maximize the individual's wealth in the worst possible state of nature.

A convenient definition of expected value EX of a random variable X in a subadditive probability space unifies the two theories of choice, one involving risk the other involving uncertainty. The trick is to define EX as the lowest possible expected value of X in an additive probability space compatible with the available information on probabilities:

$$EX = \inf_{p_j} E_j X \quad (1)$$

where $E_j X$ is the expected value of X for an additive probability function consistent with p . Equation (1) means solving the uncertainty issue by the most prudent rule: since the true expected value of X is uncertain, let us take its infimum.

As an example, let us assume a subadditive probability space with three states of nature, where:

$$p_1 = 0,2$$

$$p_2 = 0,2$$

$$p_3 = 0,2$$

$$p_{12} = 0,5$$

$$p_{13} = 0,6$$

$$p_{23} = 0,6$$

$$p_{123} = 1$$

and that the values of the random variable in the three states are $x_1 = 1$, $x_2 = 5$, $x_3 = 2$.

Indicating by p_1' , p_2' , p_3' the true probabilities of the state of nature ($p_1' + p_2' + p_3' = 1$), the true expected value of X is $p_1'x_1 + p_2'x_2 + p_3'x_3 = p_1' + 5p_2' + 2p_3'$. Since p_1' , p_2' , p_3' are uncertain, the lowest possible value for EX is obtained by taking p_2' as low as possible, namely, $p_2' = 0,2$; then, p_3' as low as possible, given p_2' , which yields $p_3' = p_{23} - p_2' = 0,4$. It remains only one possibility for p_1' , namely, $p_1' = 0,4$, and as a consequence:

$$EX = 0,4 \times 1 + 0,2 \times 5 + 0,4 \times 2 = 2,6$$

The example above indicates how the expected value of a random variable in a subadditive probability space should be computed by the safest level criterium: given the available information, states of nature with high realizations of the random variable should be weighted as less as possible. A general formula can be provided in terms of distribution functions. Given a random variable X , for every real number μ let us define:

$$F(\mu) = 1 - p(X > \mu)$$

$F(\mu)$ is the maximum possible probability of the event $(X > \mu)$. Then, compute EX according to the usual formula:

$$EX = - \int_{-\infty}^0 F(\mu) d\mu + \int_0^{\infty} (1-F(\mu)) d\mu \quad (2)$$

This is the formula of Choquet's (1955) integral. The general relation between the two ways of defining the expected value of a random variable is described in Gilboa and Schmeidler (1986).

Some important propositions about expected values in subadditive probability spaces are listed below:

Proposition 1: If X and Y are random variables in a subadditive probability space, then:

$$E(X+Y) \geq EX + EY \quad (3)$$

Proof: According to (1),

$$E(X+Y) = \inf_{P_j} E_j(X+Y) = \inf_{P_j} (E_j X + E_j Y) \geq \inf_{P_j} E_j X + \inf_{P_j} E_j Y = EX + EY \quad \text{QED.}$$

Proposition 2: If X is a random variable in a subadditive probability space, c a positive constant, then:

$$E(cX) = cEX$$

$$\text{Proof: } E(cX) = \inf_{P_j} \{E_j cX\} = \inf_{P_j} \{cE_j X\} = c \inf_{P_j} \{E_j X\} = cEX \quad \text{QED.}$$

Proposition 3: If X and Y are random variables in a subadditive probability space and if X dominates stochastically Y , i.e., $X(w) \geq Y(w)$ for every $w \in \Omega$, then $EX \geq EY$.

Proof: We first note that $E_j X \geq E_j Y$ for any additive probability function p_j . Then use (1). QED.

Proposition 4: If X is a random variable in a subadditive probability space, then:

$$E(X) + E(-X) \leq 0$$

Proof: Since $E0 = 0$, the result follows immediately from proposition 1. QED.

The importance of this proposition is that it sets both the upper lower bound and the lower upper bound of the true expected value of X , $E_{p_j} X$, that must be such that $E_{p_j} X + E_{p_j} (-X) = 0$. $E_{p_j} X$, by definition, is the upper lower bound of the true expected value of X , $E_{p_j} X$;

$$-E(-X) = \inf_{p_j} E_{p_j} (-X) = -\inf_{p_j} -(E_{p_j} X) = + \sup_{p_j} E_{p_j} X$$

That is to say that the true expected value of X lies in the uncertainty interval $EX \leq E_{p_j} X \leq -E(-X)$.

Proposition 5: Let X be a random variable in a subadditive probability space; $H(x)$ a real valued increasing and differentiable function of the real variable x ; then, if:

$$F(\mu) = E H(\mu X)$$

μ indicating a real variable, $F(\mu)$ is differentiable for every $\mu \neq 0$. For $\mu = 0$ the right side derivative is $F'_+(0) = H'(0)EX$, the left side derivative $F'_-(0) = -H'(0)E(-X)$.

Proof: Let us first assume $\mu > 0$. In this case $H(\mu X)$ is a increasing function of X , except for $\mu = 0$, where it becomes a constant. Hence, if for two additive probability functions $E_{P_i} X < E_{P_j} X$, then $E_{P_i} H(\mu X) < E_{P_j} H(\mu X)$. In short, all calculations can be made according to equation 2 in the same additive probability space. In this case E can be treated as a linear operator and, as a consequence:

$$F'(\mu) = E XH'(\mu X)$$

For $\mu < 0$ it suffices to make $\mu X = \lambda Y$, where $\lambda = -\mu$ and $Y = -X$.

Proposition 6: Let $P' = (P'_1, P'_2, \dots, P'_n)$ be an n -dimensional random vector in a subadditive probability space; $y = (y_1, y_2, \dots, y_n)$ a point in R^n ; $P' \cdot y = y_1 P'_1 + y_2 P'_2 + \dots + y_n P'_n$; and $U(W)$ a real valued concave function of the real variable W . Then:

$$G(y) = EU(P' \cdot y)$$

is a concave function of y .

Proof: Let y' and y'' indicate two points in R^n and a real number such that $0 < \mu < 1$, since $U(W)$ is concave and $P' \cdot y$ linear:

$$U(P' \cdot ((1-\mu)y' + \mu y'')) \geq (1-\mu)U(P' \cdot y') + \mu U(P' \cdot y'')$$

Hence, by proposition 3 (stochastic dominance):

$$G((1-\mu)y' + \mu y'') = EU(P' \cdot ((1-\mu)y' + \mu y'')) \geq E((1-\mu)U(P' \cdot y') + \mu U(P' \cdot y''))$$

Now, as a result of propositions 2 and 3:

$$E((1-\mu)U(P' \cdot y') + \mu U(P' \cdot y'')) > (1-\mu)EU(P' \cdot y') + \mu EU(P' \cdot y'') = (1-\mu)G(y') + \mu G(y'')$$

QED.

2) How subadditivity may lead to inertia

Before we proceed with the general discussion of portfolio choice, let us clarify why subadditive probabilities may lead to inertia. The key point is that the expected value operator E is no longer Gateaux differentiable. As a result, even if the von Neumann-Morgenstern utility function is differentiable, the portfolio indifference curves may be kinked.

As an example let us assume that a risk neutral individual is to distribute his wealth between two assets, whose unit present prices are P_1 and P_2 . His initial endowment are quantities x_1, x_2 of these assets, which is to say that his initial wealth is measured by $W = P_1 x_1 + P_2 x_2$. These assets can be purchased or sold without transaction costs, implying that the individual can choose any portfolio with quantities (y_1, y_2) as long as:

$$P_1 y_1 + P_2 y_2 \leq W = P_1 x_1 + P_2 x_2 \quad (4)$$

To guarantee the existence of an equilibrium, we shall also prohibit short sales, adding to the budget constraint (4) the inequalities:

$$y_1 \geq 0 \quad ; \quad y_2 \geq 0 \quad (5)$$

Given these constraints the individual, who is non satiable and risk neutral, will select his portfolio so as to maximize the expected value $E(y_1 P'_1 + y_2 P'_2)$ of his future wealth, P'_1, P'_2 indicating the random future asset prices.

We now assume that the individual is uncertain about the probability function in the event space. It may be either p_1 , p_2 or a convex combination of both. If it is p_1 , the expected future asset prices are $E_1P'_1$, $E_1P'_2$. If it is p_2 , these expected values change to $E_2P'_1$, $E_2P'_2$. To make the discussion interesting we shall assume that:

$$\begin{aligned} E_1P'_1 &> E_2P'_1 \\ E_2P'_2 &> E_1P'_2 \end{aligned} \tag{6}$$

What is the expected value of the individual's future wealth with a portfolio (y_1, y_2) ? All available information is that it may be either $y_1E_1P'_1 + y_2E_1P'_2$, $y_1E_2P'_1 + y_2E_2P'_2$ or some convex combination of these values. The maximin rule is to choose (y_1, y_2) in the budget constraint area so as to maximize:

$$E(y_1P'_1 + y_2P'_2) = \min \{ y_1E_1P'_1 + y_2E_1P'_2 ; y_1E_2P'_1 + y_2E_2P'_2 \}$$

The portfolio indifference curves are very easy to draw since they are homothetical, as shown in figure 1. In region I, $y_1E_1P'_1 + y_2E_1P'_2 > y_1E_2P'_1 + y_2E_2P'_2$, which implies:

$$\frac{y_1}{y_2} > \frac{E_2P'_2 - E_1P'_2}{E_1P'_1 - E_2P'_1}$$

and $E(y_1P'_1 + y_2P'_2) = y_1E_2P'_1 + y_2E_2P'_2$. The absolute value of the slope of any indifference curve in this region is given by:

$$-\frac{dy_2}{dy_1} = \frac{E_2P'_1}{E_2P'_2}$$

In region II, $y_1 E_2 P'_1 + y_2 E_2 P'_2 > y_1 E_1 P'_1 + y_2 E_1 P'_2$, which is to say that:

$$\frac{y_1}{y_2} < \frac{E_2 P'_2 - E_1 P'_2}{E_1 P'_1 - E_2 P'_1}$$

with $E(y P' + y P') = y E P' + y E P'$ and with indifference curve slopes such that:

$$-\frac{dy_2}{dy_1} = \frac{E_1 P'_1}{E_1 P'_2}$$

Inequalities (6) imply, since expected asset prices should be non negative:

$$\frac{E_1 P'_1}{E_1 P'_2} > \frac{E_2 P'_1}{E_2 P'_2}$$

which is to say that indifference curves are steeper in region II compared to region I, as in figure 1.

Now let us discuss the problem of portfolio inertia. Given the budget constraint and the present asset prices, the conclusion is that as long as the present asset prices P_1 and P_2 are such that:

$$\frac{E_1 P'_1}{E_1 P'_2} > \frac{P_1}{P_2} > \frac{E_2 P'_1}{E_2 P'_2} \quad (7)$$

the optimum portfolio will be the point of the budget frontier AB.

$P_1(y_1 - x_1) + P_2(y_2 - x_2) = 0$ in the borderline of regions I and II, namely, where:

$$\frac{Y_1}{Y_2} = \frac{E_2 P'_2 - E_1 P'_2}{E_1 P'_1 - E_2 P'_1}$$

If the initial endowment of the individual is already on this ON straight line, a small change in present asset prices, which means a rotation of his budget constraint with the fixed point N, will not change the individual optimum portfolio, as long as inequalities (7) are fulfilled. Out of these inequalities, the individual will concentrate his portfolio in a single asset, moving to a corner equilibrium, since short sales are prohibited.

Figure 1

Why a portfolio along the straight line ON is inertial, as opposed to chose in region I or region II, deserves both a mathematical and an economically intuitive explanation. The first is obvious: along the ON straight line, expected utility is not a differentiable function of the portfolio quantities. The second seems harder to generalize, but is obviously more inspiring. An on portfolio clears uncertainties. In fact, with such a portfolio

proportions, $y_1 E_1 P'_1 + y_2 E_1 P'_2 = y_1 E_2 P'_1 + y_2 E_2 P'_2$, namely, its future expected value is no longer uncertain. The general case is much more complicated. Section 4 explores the case of pure uncertainty.

How subadditive probabilities can lead to portfolio inertia was shown for a particular case by Dow and Werlang(1989). An individual must distribute his wealth W between two assets: money, which is certain, riskless but that has no yield; and a risky and uncertain stock the present price of which is indicated by P . The individual is non satiable, and risk averse. Short sales are unrestricted, so that his budget constraint is given by:

$$y_1 + P y_2 \leq W$$

y_1 and y_2 indicating the quantities of money and of the risky asset. Since utility is an increasing function of wealth the individual will operate on his budget frontier, where $y_1 = W - P y_2$, choosing y_2 so as to maximize:

$$F(y_2) = EU(y_1 + P' y_2) = EU(W + y_2 (P' - P))$$

where P' is the random future price of the stock. Now, $U(W + y_2 (P' - P))$ is an increasing function of $P' - P$. Hence, according to proposition 5, $F(y_2)$ is differentiable for every $y_2 \neq 0$, but may be non differentiable for $y_2 = 0$. For $y_2 = 0$, the right side and left side derivatives are:

$$F'_+(0) = U'(W) (E P' - P)$$

$$F'_-(0) = -U'(W) E(P' - P) = -U'(W) (P + E(-P'))$$

Expected utility will be maximum for $y_2 = 0$ if and only if

$$F'_+(0) \leq 0 \leq F'_-(0)$$

namely, if and only if:

$$EP' \leq P \leq -E(-P') \quad (8)$$

Inertia occurs if the present stock price P lies in this interval. The individual will neither buy nor sell short the risky asset, concentrating all his wealth on money. The reason is easy to understand: the individual is uncertain whether the true expected price of the stock in the future will be higher or lower than its present price.

Outside the interval (8) the individual will either buy or sell short some quantity of the stock. Now inertia is no longer possible, since $F(y_2)$ is differentiable for $y_2 \neq 0$. In the Dow-Verlang example all expected indifference curve kinks lie in the horizontal axis, as in figure 2.

Figure 2

3) Portfolio optimization

We can now present the general portfolio selection problem with subadditive probabilities. A non satiable and risk averse individual has a von Neumann-Morgenstern utility function $U(W)$, namely U is an increasing and strictly concave function of wealth W . There are n assets, the initial prices of which are described by the n -dimensional vector P . The individual is initially endowed with quantities $x \in R^n$ of these assets, so that his initial wealth is given by $W = P \cdot x$. Assets can be purchased and sold without transaction costs. Moreover, short sales are unrestricted. This is to say that any $y \in R^n$ represents a feasible portfolio as long as:

$$P \cdot y \leq P \cdot x \quad (9)$$

Future asset prices are indicated by the n -dimensional random vector P' . The problem of the individual is to choose a feasible portfolio y so as to maximize the expected utility of his future wealth:

$$F(y) = EU(P' \cdot y)$$

Formally, the problem appears the same of portfolio choice with additive probabilities. This is due to the definition of expected value of a random variable with subadditive probabilities. The difference now is that even if the utility function is differentiable, the expected utility $F(y)$ may not be. The hypothesis of risk aversion, however, avoids most of the complications of non differentiability. In fact, according to proposition 6, $F(y)$ is a concave function of y , defined in all R^n , since shorts sales are unrestricted. And a concave function defined in an open set has

a derivative in every possible direction.

Let us first describe the geometrical solution to the problem. Since the individual is non satiable, the portfolio equilibrium y_0 , assuming it exists, will lie in the budget frontier $P \cdot y = P \cdot x$. Let us indicate by:

$$B(y_0) = \{y \in R^n \mid F(y) > F(y_0)\}$$

$B(y_0)$ is the set of portfolio combinations with expected utility higher than y_0 . Obviously y_0 is an equilibrium portfolio if and only if any point of $B(y_0)$ violates the individual's budget constraint. Moreover, since $F(y)$ is concave, $B(y_0)$ is a convex subset of R^n . These observations are summarized in:

Proposition 7: A feasible portfolio y_0 is optimal if and only if the budget frontier $P \cdot (y - x) = 0$ is a supporting hyperplane of $B(y_0)$ at y_0 .

Now, the proposition above admits two subcases:

a) The supporting hyperplane of $B(y_0)$ at y_0 is unique (figure 3). In this case, any normal of the supporting hyperplane must be proportional to the present asset price vector P . This is the case where $F(y)$ is differentiable at y_0 . This is the non inertial case: any change in relative present asset prices must displace the portfolio equilibrium;

b) There are multiple supporting hyperplane of $B(y_0)$ at y_0 (figure 4). This is the case where $F(y)$ is non differentiable at y_0 . The budget frontier can rotate around the fixed point y_0 as a result of a change in relative asset prices, as long as P remains

as a normal to one of these multiple supporting hyperplanes. This is the inertial case: within certain limits, a change the portfolio composition.

Figure 3

Figure 4

To provide an analytical solution to the problem it suffices to recall the definition of directional derivative and supergradient of a concave function and to use the theorem of Kuhn and Tucker.

Let $G(y)$ be a real concave function defined in an open neighborhood of $y \in \mathbb{R}^n$; u a vector of $\mathbb{R}^n$ ($u \neq 0$). The directional derivative $G'(y, u)$, namely, the derivative of G at point y in the direction u is defined as:

$$G'(y, u) = \lim_{\lambda \rightarrow 0^+} \frac{G(y + \lambda u) - G(y)}{\lambda}$$

being a positive real variable.

One easily proves that:

i) $G'(y,u)$ exists for every $u \neq 0$ and is a superlinear function of u , i.e., $G'(y, \mu u) = \mu G'(y,u)$ for every positive real number μ and $G'(y, u_1 + u_2) \geq G'(y, u_1) + G'(y, u_2)$;

ii) $G(y)$ has its absolute maximum at y_0 if and only if $G'(y_0, u) \leq 0$ for every $u \neq 0$ in R^n ;

iii) there exists at least one vector $v = v(y) \in R^n$ such that $G'(y, u) \leq (v; u)$ for every $0 \neq u \in R^n$, $(v; u)$ indicating the euclidean inner product of v and u . Any vector v fulfilling this condition is called a supergradient of G at point y :

iv) $G(y)$ is differentiable at y_0 if and only if $G'(y, u) + G'(y, -u) = 0$ for every $u \neq 0$ in R^n . In this case, the supergradient of G at y_0 is unique and $G'(y_0, u) = (v; u)$. Conversely, if the supergradient of G at y_0 is unique, G is differentiable at y_0 .

Let us now turn back to the portfolio optimization problem. According to Kuhn and Tucker's theorem, a feasible portfolio y_0 will be optimal if and only if, for some non negative Lagrange multiplier λ :

$$F(y_0) + \lambda P.(x - y_0) = F(y) \geq F(y) + \lambda P.(x - y), \text{ for every } y \in R^n$$

The maximum of the Lagrangean, in terms of directional derivatives, can be expressed by the necessary and sufficient condition:

$$F'(y_0, u) - P.u. \leq 0 \text{ for every } u \neq 0 \text{ in } R^n.$$

since the directional derivative of $P.(x - y) = - P.u$.

Summing up, a feasible portfolio y_0 , located at the individual's budget frontier $P y = P x$ is optimal if and only if the present asset vector price P is proportional to a supergradient of $F(y)$ at y_0 . Inertia will occur if and only if this supergradient is not unique, namely, if $F(y)$ is not differentiable at y_0 .

4) Pure uncertainty

A particular case to be discussed is that portfolio choice under pure uncertainty in the sense of Frank Knight. Let $(\Omega; \mathcal{A}; p)$ be the subadditive probability space of future events, $P' = P(w)$ the n -dimensional random vector describing future asset prices. For any event $B \neq \emptyset$ such that $B^c \neq \emptyset$, $p(B) = 0$, which is to say that its true probability may lie at any point of the closed $[0, 1]$ interval. Accordingly, the expected value and the expected utility of a portfolio $y \in R^n$ are given by:

$$H(y) = E(P'y) = \inf_{w \in \Omega} \{ (P'_w y) \}$$

$$EU(P'y) = \inf_{w \in \Omega} U(P'_w y)$$

or, since $U(W)$ is an increasing continuous function of W :

$$EU(P'y) = U(H(y))$$

Summing up, an optimal portfolio is one that maximizes $H(y)$ given the individual's budget constraint. (The existence of both, $H(y)$ and of an equilibrium portfolio can be assured if short sales are restricted, namely, $y + y_0 \geq 0$ for some non negative vector y_0). The von Neumann-Morgenstern utility function is irrelevant, as long as it is increasing. This should be no surprise, since the role of the utility function is to order preferences involving risk. In the case under discussion there is no risk but only pure uncertainty.

The interesting point is that pure uncertainty can lead to anything in terms of portfolio inertia, depending on how future asset prices vary along the possible states of nature. Two extreme

possibilities are shown below. In both cases Ω is the open interval $(0,1)$, and the individual must distribute his wealth between two assets, namely, $P'(w) = (P'_1(w); P'_2(w))$. Short sales are ruled out, meaning that $y = (y_1, y_2) \geq 0$.

Example A: $P'_1(w) = w; P'_2(w) = 1-w$

$$\text{In this case, } H(y) = \inf_{0 < w < 1} \{wy_1 + (1-w)y_2\} = \min \{y_1; y_2\}$$

This is case of total inertia. The optimum portfolio combines equal quantities of the two assets, independently of the present asset prices. Portfolio indifference curves are straight angles.

Example B: $P'_1(w) = -\log w$

$$P'_2(w) = -\log(1-w)$$

$$\begin{aligned} \text{Now, } H(y) &= \inf_{0 < w < 1} \{-y_1 \log w - y_2 \log(1-w)\} \\ &= (y_1 + y_2) \log(y_1 + y_2) - y_1 \log y_1 - y_2 \log y_2. \end{aligned}$$

a differentiable function of y . The example shows that uncertainty can lead to portfolio inertia but not necessarily creates inertia.

5) Conclusions

This paper intended to address the following question: can an investor stay put under small variations of the prices of assets?

The very general answer is yes: as long as there is uncertainty, as opposed to risk.

The theory of uncertainty, as viewed by Savage(1954), was a simple reduction to subjective risk. Alternatively, we used here Schmeidler-Gilboa's uncertainty theory: the consumer maximizes expected utility with respect to subadditive probabilities.

This theory can be applied to several apparently paradoxical phenomena:

(1) Why do some large creditor banks do not sell or buy debt in the secondary market?

(2) The theory of inflationary inertia assumes that people are not Nash-equilibrium players. (See Simonsen(1987)). In a certain sense, this view is that inertia is always an out of equilibrium phenomenon. By having Nash equilibria with non additive probabilities, we find out that inflationary inertia may arise in equilibrium.

(3) Keynes's theory of investment, where "animal spirits" play a rôle, may be viewed as a reflex of uncertainty in the sense described here.

(4) The investigation of Bayesian learning of independent trials of a random variables (as, for example, tossing the same coin over and over), in connection with a subadditive prior, may lead to the intuitive conclusion that uncertainty decreases with experience:

the more the uncertain phenomenous is observed, the less uncertain it becomes.

We expect to pursue some of these problems in the future.

ENSAIOS ECONÔMICOS DA EPGE

(a partir do nº 100)

100. JUROS, PREÇOS E DÍVIDA PÚBLICA VOLUME I: ASPECTOS TEÓRICOS
- Marco Antonio C. Martins e Clovis de Faro - 1987 (esgotado)
101. JUROS, PREÇOS E DÍVIDA PÚBLICA VOLUME II: A ECONOMIA BRASILEIRA - 1971/85
- Antonio Salazar P. Brandão, Clóvis de Faro e Marco A. C. Martins - 1987 (esgotado)
102. MACROECONOMIA KALECKIANA - Rubens Penha Cysne - 1987
103. O PRÊMIO DO DÓLAR NO MERCADO PARALELO, O SUBFATURAMENTO DE EXPORTAÇÕES E O SUPERFATURAMENTO DE IMPORTAÇÕES - Fernando de Holanda Barbosa - Rubens Penha Cysne e Marcos Costa Holanda - 1987 (esgotado)
104. BRAZILIAN EXPERIENCE WITH EXTERNAL DEBT AND PROSPECTS FOR GROWTH-
Fernando de Holanda Barbosa and Manuel Sanchez de La Cal - 1987 (esgotado)
105. KEYNES NA SEDIÇÃO DA ESCOLHA PÚBLICA - Antonio M.da Silveira-1987(esgotado)
106. O TEOREMA DE FROBENIUS-PERRON - Carlos Ivan Simonsen Leal - 1987
107. POPULAÇÃO BRASILEIRA - Jessé Montello-1987 (esgotado)
108. MACROECONOMIA - CAPÍTULO VI: "DEMANDA POR MOEDA E A CURVA LM"
- Mario Henrique Simonsen e Rubens Penha Cysne-1987 (esgotado)
109. MACROECONOMIA - CAPÍTULO VII: "DEMANDA AGREGADA E A CURVA IS"
- Mario Henrique Simonsen e Rubens Penha Cysne - 1987 - (esgotado)
110. MACROECONOMIA - MODELOS DE EQUILÍBRIO AGREGATIVO A CURTO PRAZO
- Mario Henrique Simonsen e Rubens Penha Cysne-1987 (esgotado)
111. THE BAYESIAN FOUNDATIONS OF SOLUTION CONCEPTS OF GAMES - Sérgio
Ribeiro da Costa Werlang e Tommy Chin-Chiu Lee - 1987 (esgotado)
112. PREÇOS LÍQUIDOS (PREÇOS DE VALOR ADICIONADO) E SEUS DETERMINANTES;
DE PRODUTOS SELECIONADOS, NO PERÍODO 1980/1º Semestre/1986 -
- Raul Flerman - 1987
113. EMPRÉSTIMOS BANCÁRIOS E SALDO-MÉDIO: O CASO DE PRESTAÇÕES -
Clóvis de Faro - 1988 (esgotado)
114. A DINÂMICA DA INFLAÇÃO - Mario Henrique Simonsen - 1988 (esgotado)
115. UNCERTAINTY AVERSION AND THE OPTIMAL CHOICE OF PORTFOLIO -
James - Dow e Sérgio Ribeiro da Costa Werlang-1988 (esgotado)
116. O CICLO ECONÔMICO - Mario Henrique Simonsen - 1988 (esgotado)
117. FOREIGN CAPITAL AND ECONOMIC GROWTH - THE BRAZILIAN CASE STUDY-
Mario Henrique Simonsen - 1988
118. COMMON KNOWLEDGE - Sérgio Ribeiro da Costa Werlang - 1988(esgotado)
119. OS FUNDAMENTOS DA ANÁLISE MACROECONÔMICA-Prof.Mario Henrique
Simonsen e Prof. Rubens Penha Cysne - 1988 (esgotado)
120. CAPÍTULO XII - EXPECTATIVAS RACIONAIS - Mario Henrique
Simonsen - 1988 (esgotado)
121. A OFERTA AGREGADA E O MERCADO DE TRABALHO - Prof. Mario Henrique
Simonsen e Prof. Rubens Penha Cysne - 1988 (esgotado)
122. INÉRCIA INFLACIONÁRIA E INFLAÇÃO INERCIAL - Prof. Mario Henrique
Simonsen - 1988 (esgotado)
123. MODELOS DO HOMEM: ECONOMIA E ADMINISTRAÇÃO - Antonio Maria da
Silveira - 1988
124. UNDERINVOICING OF EXPORTS, OVERINVOICING OF IMPORTS, AND THE
DOLLAR PREMIUM ON THE BLACK MARKET - Prof. Fernando de Holanda Barbosa,
Prof. Rubens Penha Cysne e Marcos Costa Holanda - 1988 (esgotado)

125. O REINO MÁGICO DO CHOQUE HETERODOXO - Fernando de Holanda Barbosa
Antonio Salazar Pessoa Brandão e Clovis de Faro - 1988 (esgotado)
126. PLANO CRUZADO: CONCEPÇÃO E O ERRO DE POLÍTICA FISCAL - Rubens
Penha Cysne - 1988
127. TAXA DE JUROS FLUTUANTE VERSUS CORREÇÃO MONETÁRIA DAS PRESTAÇÕES:
UMA COMPARAÇÃO NO CASO DO SAC E INFLAÇÃO CONSTANTE - Clovis de
Faro - 1988
128. CAPÍTULO II - MONETARY CORRECTION AND REAL INTEREST ACCOUNTING
- Rubens Penha Cysne - 1988
129. CAPÍTULO III - INCOME AND DEMAND POLICIES IN BRAZIL - Rubens
Penha Cysne - 1988
130. CAPÍTULO IV - BRAZILIAN ECONOMY IN THE EIGHTIES AND THE DEBT
CRISIS - Rubens Penha Cysne - 1988
131. THE BRAZILIAN AGRICULTURAL POLICY EXPERIENCE: RATIONALE AND
FUTURE DIRECTIONS - Antonio Salazar Pessoa Brandão - 1988
132. MORATÓRIA INTERNA, DÍVIDA PÚBLICA E JUROS REAIS - Maria Silvia
Bastos Marques e Sérgio Ribeiro da Costa Werlang - 1988
133. CAPÍTULO IX - TEORIA DO CRESCIMENTO ECONÔMICO - Mario Henrique
Simonsen - 1988
134. CONGELAMENTO COM ABONO SALARIAL GERANDO EXCESSO DE DEMANDA -
- Joaquim Vieira Ferreira Levy e Sérgio Ribeiro da Costa Werlang - 1988
135. AS ORIGENS E CONSEQUÊNCIAS DA INFLAÇÃO NA AMÉRICA LATINA -
Fernando de Holanda Barbosa - 1988
136. A CONTA CORRENTE DO GOVERNO - 1970-1988 - Mario Henrique
Simonsen - 1988
137. A REVIEW ON THE THEORY OF COMMON KNOWLEDGE
- Sérgio Ribeiro da Costa Werlang - 1989
138. MACROECONOMIA
- Fernando de Holanda Barbosa - 1988 (esgotado)
139. TEORIA DO BALANÇO DE PAGAMENTOS: UMA ABORDAGEM SIMPLIFICADA -
- João Luiz Tenreiro Barroso - 1989
140. CONTABILIDADE COM JUROS REAIS - RUBENS PENHA CYSNE - 1989
141. "CREDIT RATIONING AND THE PERMANENT INCOME HYPOTHESIS" - Vicente Madrigal,
Tommy Tan, Daniel Vicent, Sérgio Ribeiro da Costa Werlang - 1989
142. "A AMAZÔNIA BRASILEIRA" - Ney Coe de Oliveira - 1989
143. DESÁGIO DAS LFTs E A PROBABILIDADE IMPLÍCITA DE MORATÓRIA
Maria Silvia Bastos Marques e Sérgio Ribeiro da Costa Werlang - 1989
144. THE LDC DEBT PROBLEM: A GAME-THEORETICAL ANALYSIS
Mario Henrique Simonsen e Sérgio Ribeiro da Costa Werlang - 1989
145. ANÁLISE CONVEXA NO R^n - Mario Henrique Simonsen - 1989
146. A CONTROVÉRSIA MONETARISTA NO HEMISFÉRIO NORTE
Fernando de Holanda Barbosa - 1989
147. FISCAL REFORM AND STABILIZATION: THE BRAZILIAN EXPERIENCE - Fernando de Holanda
Barbosa, Antônio Salazar Pessoa Brandão e Clovis de Faro - 1989

148. RETORNOS EM EDUCAÇÃO NO BRASIL: 1976-1986
Carlos Ivan Simonsen Leal e Sérgio Ribeiro da Costa Werlang - 1989
149. PREFERENCES, COMMON KNOWLEDGE, AND SPECULATIVE TRADE - James Dow,
Vicente Madrigal, Sérgio Ribeiro da Costa Werlang - 1990
150. EDUCAÇÃO E DISTRIBUIÇÃO DE RENDA
Carlos Ivan Simonsen Leal e Sérgio Ribeiro da Costa - 1990
151. OBSERVAÇÕES À MARGEM DO TRABALHO "A AMAZÔNIA BRASILEIRA" - Ney
Coe de Oliveira - 1990
152. PLANO COLLOR: UM GOLPE DE MESTRE CONTRA A INFLAÇÃO?
- Fernando de Holanda Barbosa - 1990
153. O EFEITO DA TAXA DE JUROS E DA INCERTEZA SOBRE A CURVA DE PHILLIPS
DA ECONOMIA BRASILEIRA - Ricardo de Oliveira Cavalcanti - 1990
154. PLANO COLLOR: CONTRA FACTUALIDADE E SUGESTÕES SOBRE À CONDUÇÃO
DA POLÍTICA MONETÁRIA-FISCAL - Rubens Penha Cysne - 1990
155. DEPÓSITOS DO TESOURO: NO BANCO CENTRAL OU NOS BANCOS COMERCIAIS?
Rubens Penha Cysne - 1990
156. SISTEMA FINANCEIRO DE HABITAÇÃO: A QUESTÃO DO DESEQUILÍBRIO DO
FCVS - Clovis de Faro - 1990
157. COMPLEMENTO DO FASCÍCULO Nº 151 DOS "ENSAIOS ECONÔMICOS" (A AMA-
ZÔNIA BRASILEIRA) - Ney Coe de Oliveira - 1990
158. POLÍTICA MONETÁRIA ÓTIMA NO COMBATE À INFLAÇÃO
- Fernando de Holanda Barbosa - 1990
159. TEORIA DOS JOGOS - CONCEITOS BÁSICOS - Mario Henrique Simonsen -
- 1990
160. O "MERCADO ABERTO BRASILEIRO: ANÁLISE DOS PROCEDIMENTOS OPERACION-
AIS - Fernando de Holanda Barbosa - 1990
161. A RELAÇÃO ARBITRAGEM ENTRE A OPTN CAMBIO E A ORTN MONETÁRIA -
- Luiz Guilherme Schymura de Oliveira - 1990
162. SUBADDITIVE PROBABILITIES AND PORTFOLIO INERTIA - Mario Henrique
Simonsen e Sérgio Ribeiro da Costa Werlang - 1990
