

Fiscal Reform and Government Debt in Japan: A Neoclassical Perspective

Gary Hansen (UCLA) and Selo İmrohorođlu (USC)

May 10, 2013

Table of Contents

- 1 Introduction
- 2 Model Economy
- 3 Calibration
- 4 Quantitative Experiments
- 5 Conclusion

Basic Issue

- Two significant challenges faced by Japan
 - High debt to output ratio (close to 150%).
 - Projected increase in government expenditures due to aging population.
 - Spending to output projected to rise by 7% due to increases in pension and health spending.
- We explore size and consequences of fiscal responses to this problem.

High Debt

Figure : Net Debt to GNP Ratio

Aging Population

Figure : Dependency Ratios

Implications of Aging Population

Fukawa and Sato (2009)

Figure : Government Expenditures to GNP Ratios

What We Do

- Formulate and calibrate neoclassical growth model of Japan.
- Calculate effects of alternative fiscal policies designed to achieve fiscal balance.
- How large must tax rates on labor and/or consumption be to achieve this goal?
- First consider reducing transfers (lump taxes) and then consider distorting taxes.

What We Do

- Hayashi and Prescott (2002) and Chen, İmrohorođlu and İmrohorođlu (2006).
- Economic agents have perfect foresight.
- Characterize how model performs from 1981-2010.
 - Take as exogenous TFP, tax rates, government consumption, transfers and population.
 - Use observed values 1981-2010.
- Use model to forecast from 2011 and beyond.
 - Government projections for population to 2050.
 - Forecasts of Fukawa and Sato (2009) of G/Y and TR/Y to 2050.

Features of Model

- Government debt is introduced with bond price (interest rate) endogenous.
 - Government bonds enter utility function \Rightarrow rate of return dominance.
- Endogenous labor choice \Rightarrow consumption and labor income taxes are distorting.
- “Fiscal Sustainability Rule” insures that intertemporal government budget constraint is satisfied.

Related Literature

 - Experiment with policies to eliminate budget deficit in near future by increasing consumption tax.
- İmrohoroğlu and Sudo, “Will a Growth Miracle Reduce Debt in Japan”
 - Assess possibility that high TFP growth could eliminate government debt.

Model: Government Budget

$$G_t + TR_t^* + B_t = \eta_t q_t B_{t+1} + \tau_{c,t} C_t + \tau_{h,t} W_t h_t \\ + \tau_{k,t} (r_t - \delta) K_t + \tau_{b,t} (1 - q_{t-1}) B_t.$$

$$l_t = \begin{cases} 1 & \text{if } B_s / Y_s \geq b_{\max} \text{ for some } s \leq t, \\ 0 & \text{otherwise} \end{cases}$$

$$D_t = \kappa l_t (B_t - \bar{B}_t),$$

$$TR_t^* = TR_t - D_t$$

Model: Household's Problem

$$\max \sum_{t=0}^{\infty} \beta^t N_t \left[\log C_t - \alpha \frac{h_t^{1+1/\psi}}{1+1/\psi} + \phi \log(\mu_t + B_{t+1}) \right]$$

subject to

$$\begin{aligned} & (1 + \tau_{c,t}) C_t + \eta_t K_{t+1} + q_t \eta_t B_{t+1} \\ & = (1 - \tau_{h,t}) W_t h_t + [(1 + (1 - \tau_{k,t})(r_t - \delta))] K_t \\ & + [1 - (1 - q_{t-1})\tau_{b,t}] B_t + TR_t, \end{aligned}$$

Model: Firm's Problem

$$\begin{aligned}N_t Y_t &= A_t (N_t K_t)^\theta (N_t h_t)^{1-\theta} \\ N_{t+1} K_{t+1} &= (1 - \delta) N_t K_t + N_t X_t \\ A_{t+1} &= \gamma_t A_t\end{aligned}$$

Stationary Equilibrium Conditions

Given a per capita variable Z_t we obtain its detrended counterpart

$$z_t = \frac{Z_t}{A_t^{1/(1-\theta)}}.$$

- First order conditions and market clearing conditions combine to give 10 equations in 10 unknowns $\{c_t, x_t, h_t, y_t, k_{t+1}, b_{t+1}, d_t, q_t, w_t, r_t\}$ for each period t .
- Computation Objective: Find value for k_1 such that sequence converges to steady state.

Population and Labor Input

- N_t = working age population between the ages of 20 and 69
- Use actual values for 1981-2010
- Use official projections for 2011-2050
- Population constant after 2050
- h_t is employment per working age population multiplied by average weekly hours worked divided by 98 (discretionary hours available per week).

National Accounts: Hayashi and Prescott (2002)

Table : Adjustments to National Account Measurements

$C =$ Private Consumption Expenditures

$I =$ Private Gross Investment
+ Change in Inventories
+ Net Exports
+ Net Factor Payments from Abroad

$G =$ Government Final Consumption Expenditures
+ General Government Gross Capital Formation
+ Government Net Land Purchases
– Book Value Depreciation of Government Capital

$Y = C + I + G$

Government Accounts

- Public health expenditures in Japan are included in G_t .
- TR_t , includes social benefits (other than those in kind, which are in G_t ,) that are mostly public pensions, plus other current net transfers minus net indirect taxes.
- 8.1% of output is added to TR_t since modeling of flat tax rates ignores deductions and exemptions.

Tax Rates

- $\tau_{h,t}$, are average marginal labor income tax rates estimated by Gunji and Miyazaki (2011).
- Last value is 0.324 for 2007 and we assume that this remains constant thereafter.
- $\tau_{k,t}$, is constructed following methodology in Hayashi and Prescott (2002).
- Last value is 0.3557 for 2010 and we assume that this remains constant thereafter.

Tax Rates, continued

- Tax Rate on Consumption, $\tau_{c,t}$
 - 0% 1981-1988
 - 3% 1989-1996
 - 5% 1997-2013
 - 8% 2014
 - 10% 2015 and beyond.
- Tax Rate on Bond Interest, τ_b , 20% for all time periods.

Tax Rates, continued

Figure : Tax Rates

Technology Parameters

- $A_t = Y_t / (K_t^\theta h_t^{1-\theta})$.
- $\theta = 0.378$, which is the average value from 1981-2010.
- $\gamma_t = A_{t+1} / A_t$, comes from the actual data between 1981 and 2010.
- $\gamma_t = 1.015^{1-\theta}$. for 2011 and beyond.
- $\delta = 0.0842$, which is the average value from 1981-2010.

Preference Parameters

- Five preference parameters, β , α , ψ , ϕ , and μ .
- $\mu = \mu_t / A_t^{1/(1-\theta)} = 1.1$.
- $\psi = 0.5$, the Frisch elasticity of labor supply estimated by Chetty et al (2012).

Preference Parameters, continued

For β , α , and ϕ , use equilibrium conditions to obtain a value for each year, and then average over the sample:

$$\beta_t = \frac{(1 + \tau_{c,t+1}) \gamma_t^{1/(1-\theta)} c_{t+1}}{(1 + \tau_{c,t}) c_t \left[1 + (1 - \tau_{k,t+1}) \left(\theta \frac{y_{t+1}}{k_{t+1}} - \delta \right) \right]}$$

$$\alpha_t = \frac{h_t^{-1/\psi} (1 - \tau_{h,t}) (1 - \theta) y_t}{(1 + \tau_{c,t}) c_t h_t}$$

$$\phi_t = \eta_t (\mu + b_{t+1}) \left[\frac{q_t \gamma_t^{1/(1-\theta)}}{(1 + \tau_{c,t}) c_t} - \frac{\beta_t [1 - (1 - q_t) \tau_{b,t+1}]}{(1 + \tau_{c,t+1}) c_{t+1}} \right].$$

Bond Price

Need empirical counterpart to q_t :

$$q_t = \frac{B_{t+1}/F_t}{(B_{t+1} + P_{t+1})/F_{t+1}}.$$

- B_t is beginning of period debt.
- P_t is interest payments made in period t .
- F_t is the GNP deflator.

Bond Price, continued

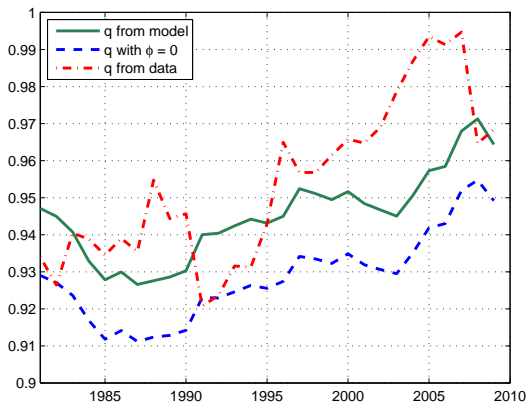

Figure : Bond Prices

Bond Price, continued

Figure : Returns on Capital and Bonds

Structural Parameters

Table : Calibration of Structural Parameters

Parameter	Value	
θ	0.3783	Data Average
δ	0.0842	Data Average
β	0.9677	FOC, 1981-2010
α	22.6331	FOC, 1981-2010
ψ	0.5	Chetty et al (2012)
ϕ	0.063	FOC, 1981-2010
μ	1.1	fit q_t for 1981-2010

Fiscal Sustainability

$$d_t = \kappa l_t (b_t - \bar{b} \bar{y}),$$
$$l_t = \begin{cases} 1 & \text{if } B_s/Y_s \geq b_{\max} \text{ for some } s \leq t, \\ 0 & \text{otherwise} \end{cases}$$

- $\bar{b} = 0.6$
- Consider $b_{\max} = 200\%$, 250% and 300% .
- Japan already near 150% .
- Different value of κ for each b_{\max} .

Tax Wedge

From first order condition for labor, can define

$$1 - \tau_t \equiv \frac{1 - \tau_{h,t}}{1 + \tau_{c,t}}$$
$$\Rightarrow \tau_t = \frac{\tau_{c,t} + \tau_{h,t}}{1 + \tau_{c,t}}$$

Government Finance in Steady State

Combination of Taxes

Implementation of Tax Increases

$$\tau_{x,t} = \begin{cases} \tau_{x,last} & \text{if } B_s/Y_s \leq b_{\max} \text{ for all } s \leq t \\ \bar{\tau}_x + \pi & \text{if } B_s/Y_s > b_{\max} \text{ for some } s \leq t \text{ and } B_t/Y_t > \bar{b} \\ \bar{\tau}_x & \text{if } B_t/Y_t \leq \bar{b}. \end{cases}$$

where $x = c$ or h and $t \geq 2015$.

- π is chosen as the smallest increment that leads to the activation of the second trigger (convergence to steady state).

Increase Consumption Tax Only

Figure : Consumption Tax Experiment 1

Increase Both Consumption and Labor Tax

Use Consumption Tax to Retire Debt, Increase Labor Tax to 45%.

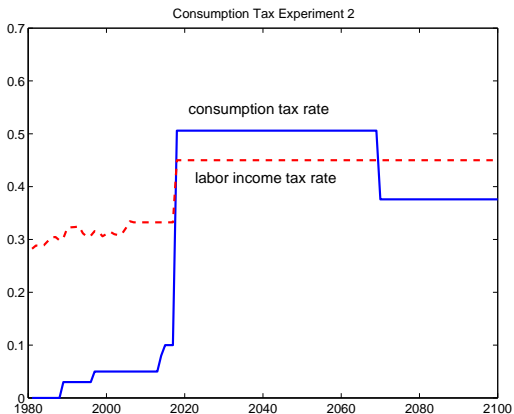

Figure : Consumption Tax Experiment 2

Increase Both Consumption and Labor Tax

Use Labor Tax to Retire Debt, Increase Consumption Tax to 40%.

Effective Tax Distortion

Figure : Effective Tax Rate

Conclusion

- Soaring debt to GNP ratio implies fiscal “day of reckoning” is soon—around 2020.
- Costs of aging population require large nearly permanent increases in tax rates:
 - Consumption tax: permanent increase to 48% with additional 12% during transition.
 - Both consumption and labor tax: permanent increase to 40%, smaller additional increase during transition.

Conclusion

- Other options to explore:
 - Broaden tax base: 8.1% of GNP potential.
 - Social security and health insurance reform.
 - Increase fertility and/or allow immigration.
 - Encourage female labor force participation.
 - Reduce spending.
